

Smart Door Lock System

Secure Access Control With PIN Authentication

This project is a cybernetic security system in the form of a PIN based smart door lock that interacts with user input through a set of push buttons. The system processes each button press using a microcontroller, storing and verifying a 4-digit password to determine whether to unlock or keep the door secured by controlling a servo motor. In addition to access control, the system provides responsive feedback through an LCD display, buzzer, and LED indicators to communicate system status and security conditions. When powered on, the system begins in a locked state, displaying its status and waiting for user input. As digits are entered, the system tracks progress and verifies the full PIN once all four digits are received. If the correct password is entered, the servo unlocks
